Abstract. In the ternary system Se / Bi / Cl a new polycation containing phase besides the already known Se$_4$[Bi$_4$Cl$_{14}$] Se$_8$[Bi$_4$Cl$_{14}$], and Se$_{10}$[Bi$_5$Cl$_{17}$] was discovered. Red, transparent, plate shaped crystals of Se$_{10}$[Bi$_4$Cl$_{14}$] were formed by reaction of Se / SeCl$_4$ / BiCl$_3$ in 15 / 1 / 8 molar ratio in evacuated glass ampoules applying a temperature gradient from 90 to 80 °C. The crystal structure consists of bicyclic Se$_{10}^{2+}$ cations and of layered chloridobismutate anions with the cations located between the anionic planes. The atoms of the cation form a six membered ring with a Se$_4$ chain bridging over the 1,4 positions of the Se$_6$ ring. The anions are made up of BiCl$_7$ polyhedra connected via common edges to layers 2$^-$$^2$[Bi$_4$Cl$_{14}$]$^{2-}$. Se$_4$[Bi$_4$Cl$_{14}$], Se$_8$[Bi$_4$Cl$_{14}$], Se$_{10}$[Bi$_4$Cl$_{14}$], and Te$_8$[Bi$_4$Cl$_{14}$] all contain an anion of identical formula and two-dimensional connectivity, but these polymeric chloridobismutates are not isostructural. The structural differences are discussed on basis of the different topologies of the nets made up by the Bi atoms.
Introduction
Bismuth trichloride is a strong Lewis acid. It reacts with chloride ion donors under formation of chloridobismutates. [BiCl$_4$]$^-$ is formally the first product, but since Bi$^{3+}$ ions prefer higher coordination numbers between six and eight, it is generally observed that variable amounts of BiCl$_3$ associate with tetrachloridobismutate under formation of chloridobismutates of higher nuclearity. The weak donor strength of these chloridobismutates is obvious in their ability to stabilize “naked” polycationic clusters of the elements of the chalcogens [1]. In the ternary system Se / Bi / Cl three compounds containing polycationic clusters were already discovered: Se$_4$[Bi$_4$Cl$_{14}$], containing the square planar Se$_4^{2+}$ ion [2], Se$_8$[Bi$_4$Cl$_{14}$], containing the bicyclic Se$_8^{2+}$ ion [2], and Se$_{10}$[Bi$_5$Cl$_{17}$] with the bicyclic Se$_{10}^{2+}$ cluster ion [3]. We discovered a fourth phase in this system and report on the synthesis and structure of Se$_{10}$[Bi$_4$Cl$_{14}$].

Experimental
Bismuth and Selenium were used as commercial products. Bismuth was purified by melting under argon protecting gas and decanting the melt from the black residue. SeCl$_4$ and BiCl$_3$ were prepared by reaction of the elements with Cl$_2$. The chlorine gas was purified by condensing to the liquid state at –75 °C in a U-shaped vessel. The Cl$_2$ gas stream for the chlorination reaction was established by bubbling argon gas through the cold, liquid chlorine. SeCl$_4$ and BiCl$_3$ were both sublimated in the Cl$_2$/Ar stream. All further manipulations like charging and opening of the reaction ampoules were performed in an argon filled glove box.

Glass ampoules of 12 cm length and 1.4 cm diameter were filled with Se, SeCl$_4$, and BiCl$_3$ in the molar ratio 15 / 1 / 8 in a total amount of 300 mg. The ampoules were evacuated, sealed and placed in a horizontal tube furnace. After keeping at 80 °C for 4 hours, a temperature gradient 90 to 80 °C was applied along the ampoule for 36 hours. Besides the main products Se$_4$[Bi$_4$Cl$_{14}$] and Se$_{10}$[Bi$_5$Cl$_{17}$], red transparent plate shaped crystals were deposited along the walls of the reaction ampoule.

Crystals were isolated by immersing in cold perfluorinated oil. Diffraction data were recorded with a Bruker Nonius CCD diffractometer at low temperature generated with a cold nitrogen stream. The space group was derived from the reciprocal lattice extinctions as $P2_12_12_1$ and the non-centrosymmetry was confirmed during the refinements. The structure was solved by direct methods [4] and refined with anisotropic displacement parameters for all atoms [5]. A Flack $x$ parameter of –0.042(4) showed the absence of inversion twinning [6]. An empirical
absorption correction was applied to the data [7]. Further crystallographic data for the crystal structure determination have been deposited with the Fachinformationszentrum Karlsruhe under the deposit number CSD-421619 [8]. For the graphical representations the program DIAMOND was used [9].

Results and Discussion

Se_{10}[Bi_4Cl_{14}] is formed in the reaction of Se, SeCl_4, and BiCl_3 besides the related phases Se_4[Bi_2Cl_{14}], Se_{10}[Bi_3Cl_{17}] and Se_8[Bi_2Cl_{14}]. Small differences in the reaction conditions favour the formation of one of the different compounds. For the synthesis of Se_{10}[Bi_4Cl_{14}], the reaction conditions were found to be optimal at a Se / SeCl_4 / Bi ratio of 15 / 1 / 8 and a temperature of 90 °C. The crystals are deposited from the gas phase and can be distinguished visually by their thin platy shape from the neighbouring phases.

The crystal structure consists of discrete Se_{10}^{2+} cations and of polymeric chloridobismutate anions \(^{2_\infty}[Bi_4Cl_{14}]^{2-}\). The cation (Fig. 1) is built of a six-membered ring in boat conformation bearing a Se_4 chain bridging over the 1,4 positions of the Se_6 ring. The Se–Se bonds show the typical separation in short bonds around 2.29 Å at the two-coordinated Se atoms and long bonds around 2.43 Å at the three-coordinated Se atoms. The Se–Se–Se angles are almost equalised in the narrow range between 99.73(4) and 102.68(4) °. The structure of the cation is thus analogous to the ions found in the structures of Se_{10}[SbF_6]_2 [10], Se_{10}[AlCl_4]_2 [10], Se_{10}[SO_3F]_2 [11], and Se_{10}[Bi_5Cl_{17}] [3]. The crystal structure is acentric. Since the structure of the Se_{10}^{2+} ion allows only for a twofold axis as the only symmetry operation, which is approximately fulfilled in the presented structure, the ion is enantiomorphic.

The Bi–Cl bonds in the chloridobismutate anion are spread over a wide range beginning from 2.490(2) Å (Bi(1)–Cl(1)). A first large gap in the bond lengths is present after Bi(3)–Cl(2)^IV = 3.379(2) Å (Fig. 2). If all Bi–Cl distances up to this limit are taken into account, all four independent Bi atoms obtain coordination polyhedra with coordination number seven. These polyhedra are connected via common edges to layers spread out in the crystallographic a-b plane. The Se_{10}^{2+} cations are embedded between the layers of the polymeric anions (Fig. 3).
Four compounds are now known, which all contain the [Bi₄Cl₁₄]²⁻ anion, Se₄[Bi₄Cl₁₄], Se₈[Bi₄Cl₁₄], Se₁₀[Bi₄Cl₁₄], and Te₈[Bi₄Cl₁₄] [12]. It is remarkable that the anions in all four structures are not isostructural, despite the identical formula and the shared structural feature of forming two-dimensional arrangements. The differences between the anions, but also their relationship, can be understood if, for simplification, only the arrangement of the Bi atoms is considered. The respective nets of the Bi atoms are depicted in Fig. 4. The nets present in the structures of the selenium containing compounds Se₈[Bi₄Cl₁₄] (a), Se₁₀[Bi₄Cl₁₄] (b), and Se₄[Bi₄Cl₁₄] (c) are closely related. They show an arrangement of the Bi atoms analogous to the motif of the oxide ions in the rutile structure. This is in line with the tetragonal symmetry of Se₄[Bi₄Cl₁₄] as the representative with the highest symmetry. Orthorhombic Se₁₀[Bi₄Cl₁₄] and triclinic Se₈[Bi₄Cl₁₄] are distorted variants. The three nets share the same connection type, expressed by the Schlafli symbol 3³4² [13]. The arrangement of triangles and quadrangles is different in the net belonging to the structure of Te₈[Bi₄Cl₁₄] (d), but the connection type 3³4² is also valid for this arrangement.

Acknowledgement

The authors thank Dr. Jörg Daniels, Inorganic Chemistry Institute of University of Bonn, for encouraging help with the isolation of suitable crystals and for the recording of the diffraction data set.
